Overview

NetTimeLogic's IRIG Slave Clock is a full hardware (FPGA) only implementation of a synchronization core able to synchronize to a IRIG-B input.

The whole time frame decoding, algorithms and calculations are implemented in the core, no CPU is required. This allows running IRIG synchronization completely independent and standalone from the user application. The core can be configured either by signals or by an AXI4Lite-Slave Register interface.

Key Features:

- IRIG-B and IRIG-G Slave Clock
- Supports IRIG-B006 and IRIG-G006 format (compatible with B004, B005, B006 and B007 IRIG-B Masters) with PWM encoded DCLS
- Optionally supports IRIG-B126 and IRIG-G146 format (compatible with B124, B125, B126 and B127 IRIG-B Masters) with AM encoded AC (requires an ADC)
- IRIG-BXX0-3 support with manual year setting and automatic year increment (XX0-XX3 lack year information)
- IRIG decoding and time format conversion
- IRIG supervision
- Optional support all IRIG-Bxx0 - Bxx7 codes, changeable at runtime
- Optional support Control Bits for IRIG-Bxx0/Bxx1/Bxx4/Bxx5
- Input delay compensation
- Cable delay compensation
- Additional seconds correction to convert between UTC and TAI time (or any other time base)
- Synchronization accuracy: +/- 25ns (DCLS)
- AXI4Lite register set or static configuration
- Timestamp resolution with 50 MHz system clock: 20ns (DCLS)
- Hardware PI Servo

Revision History

This table shows the revision history of this document.

Version	Date	Revision
0.1	20.10.2016	First draft
1.0	28.10.2016	First release
1.1	20.12.2017	Status interface added
1.2	26.06.2018	Added Control Bits
1.3	16.02.2022	IRIG-G added
1.4	03.01.2023	Added Vivado upgrade version description
1.5	17.01.2025	Added selectable IRIG Code and Manual Year
1.6	28.01.2025	Added AM Mode

1 Introduction

1.1 Context Overview

The IRIG Slave Clock is meant as a co-processor handling an IRIG input.
It takes an IRIG input, converts the pulse width modulated (PWM) data stream into a binary format, decodes the BCD encoded time of day and converts it to a second/nanosecond format. In parallel it takes a timestamp when the reference marker is detected. It then calculates the offset and drift of the local clock against the reference clock from the IRIG master and corrects it. It also extracts the Control Bits for processing by the user.
The IRIG Slave Clock is designed to work in cooperation with the Counter Clock core from NetTimeLogic (not a requirement). It contains an AXI4Lite slave for configuration and status supervision from a CPU, this is however not required since the IRIG Slave Clock can also be configured statically via signals/constants directly from the FPGA.

Optionally the IRIG Slave Clock can also handle AC/AM encoded IRIG-B/IRIG-G with an external ADC and an AC/AM to DCLS converter. Contact us for details
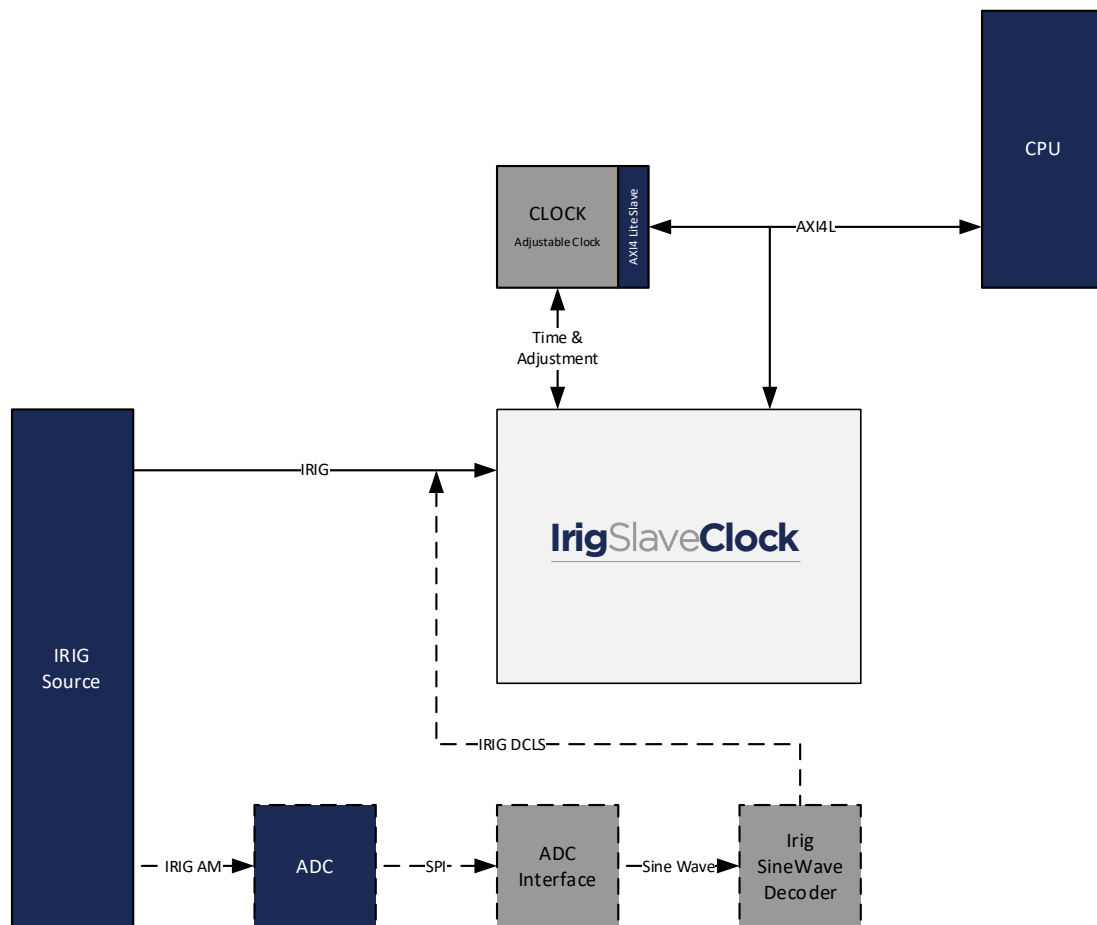

Figure 1:   Context Block Diagram

1.2 Function

The IRIG Slave Clock takes an IRIG signal, decodes the IRIG input data stream and converts the signal from a DCLS encoded PWM signal to a BCD encoded time and converts it then into UTC in time of day format. In parallel it detects the start of second condition and generates a PPS. Then it converts the UTC time in time of day format into TAI format in seconds since 1.1.1970 without leap seconds. It also takes a timestamp of the rising edge of the PPS. After 2 consecutive correct PPS timestamps are taken and 2 consecutive IRIG time frames were decoded, the calculation of offset and drift is started. For offset correction an additional cable delay and time base correction value is added to the calculation to compensate the propagation delay between the master and slave and the offset between the different time-domains (UTC, TAI etc.). Offset and drift corrections are feed to the PI servo loops of the Adjustable Counter Clock Core and the output of the Servo loop used for the next calculations. In case of an error the correction is stopped until

two IRIG time frames were correctly decoded again after the error flag was de-asserted.

1.3 Architecture

The core is split up into different functional blocks for reduction of the complexity, modularity and maximum reuse of blocks. The interfaces between the functional blocks are kept as small as possible for easier understanding of the core.
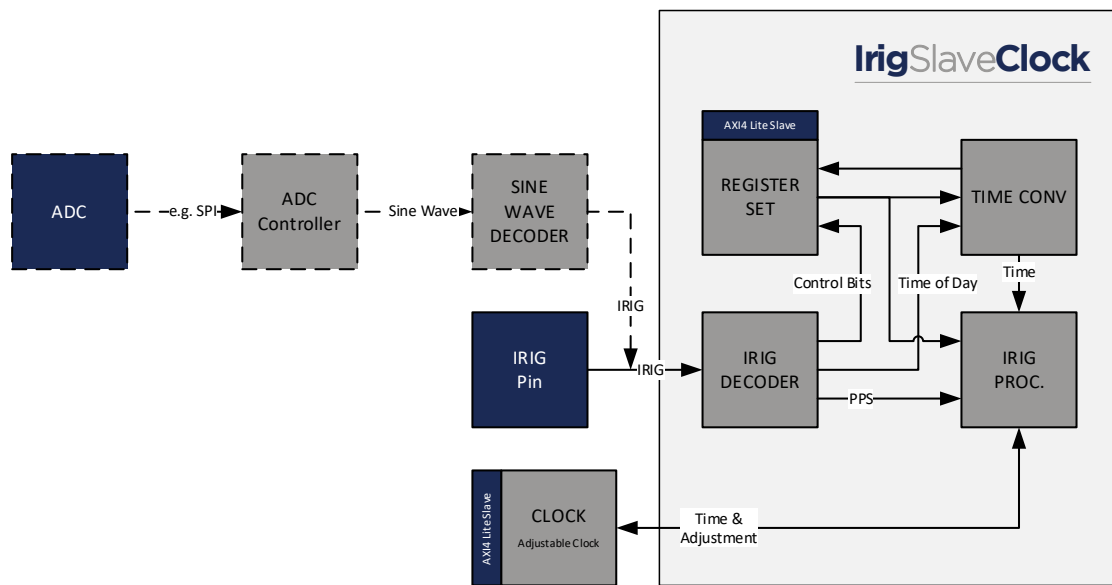

Figure 2:   Architecture Block Diagram

Register Set
This block allows reading status values and writing configuration.

IRIG Decoder
This block decodes the IRIG input data stream and converts the signal from a DCLS encoded PWM signal to a BCD encoded time and converts it then into UTC in time of day format. In parallel it detects the start of second condition and generates a PPS and extracts the Control Bits.

Time Converter
This block converts the UTC time in time of day format into TAI format in seconds since 1.1.1970 without leap seconds

IRIG Processor

This block takes a timestamp of the rising edge of the IRIG marker, takes the propagation delay of the cable into account, calculates the offset and the drift and adjusts the local clock.

2 IRIG Basics

2.1 Interface

IRIG is a very simple interface and can be either DC Level shift or Amplitude modulated on a base frequency and has Pulse Width modulated symbols. It is a continuous data stream of "One", "Zero" and "Mark" symbols with symbol patterns to mark the beginning of a time frame. The reference point is the edge to the active level of the reference mark; this shall be at the second overflow of the reference clock. This edge shall be very accurate compared to the other edges of the symbols of a time frame. A time frame can be repeated from multiple times a second to once every multiple second, depending on the IRIG code used. Also the number of bits in a time frame varies from 60 to 100 bits and the time frame content is depending on the IRIG code. This core supports the IRIG-B B007 and IRIG-G G006 code (optionally also the other codes) which generates a time frame of 100 bits once every second.

An IRIG-B time frame in B007/B127 format contains the following:

- Second (BCD encoded)
- Minute (BCD encoded)
- Hour (BCD encoded)
- Day of Year (BCD encoded)
- Year (BCD encoded)
- Seconds of Day (Straight Binary encoded)
Figure 3:   IRIG-B B007/B127 time frame

The B007/B127 format is in principle compatible with B004/B124, B005/B125, B006/B126 and B007/B127 IRIG-B Slaves which only check the time fields.

An IRIG-B time frame in B004/B124 format contains the following:
- Second (BCD encoded)
- Minute (BCD encoded)
- Hour (BCD encoded)
- Day of Year (BCD encoded)
- Year (BCD encoded) (Control Bits 0:8)
- Control Bits 9:17
- Control Bits 18:26
- Seconds of Day (Straight Binary encoded) - unused
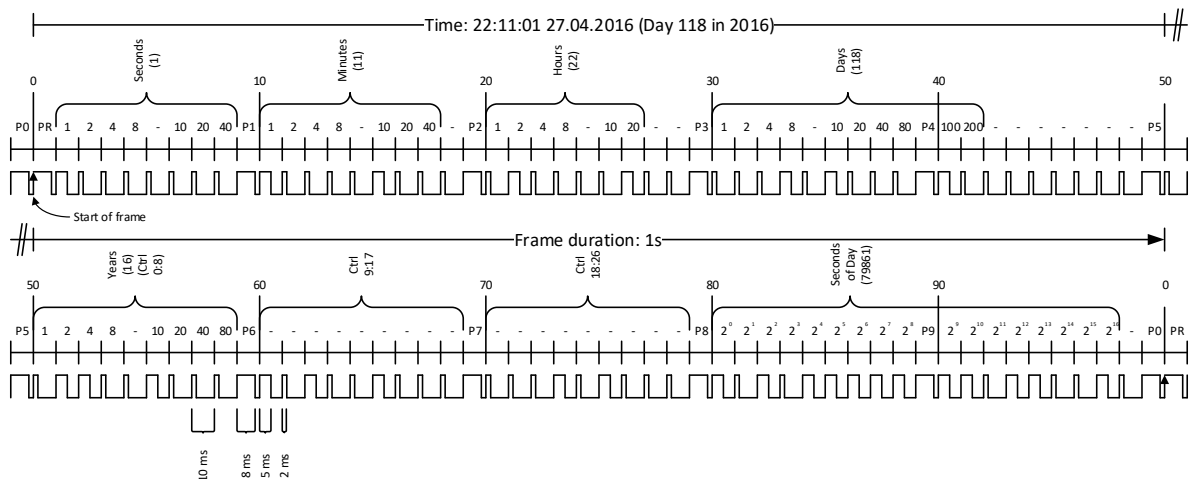

Figure 4:   IRIG-B B004/B124 time frame

So, in addition to IRIG-B007/B127 Control Bits are transferred which can be used to send user data or IEEE1344 or C37.118 Information to the Slave.

An IRIG-G time frame in G006/B146 format contains the following:
- Second (BCD encoded)
- Minute (BCD encoded)
- Hour (BCD encoded)
- Day of Year (BCD encoded)
- Year (BCD encoded)
- Milliseconds (BCD encoded)
- Control Bits
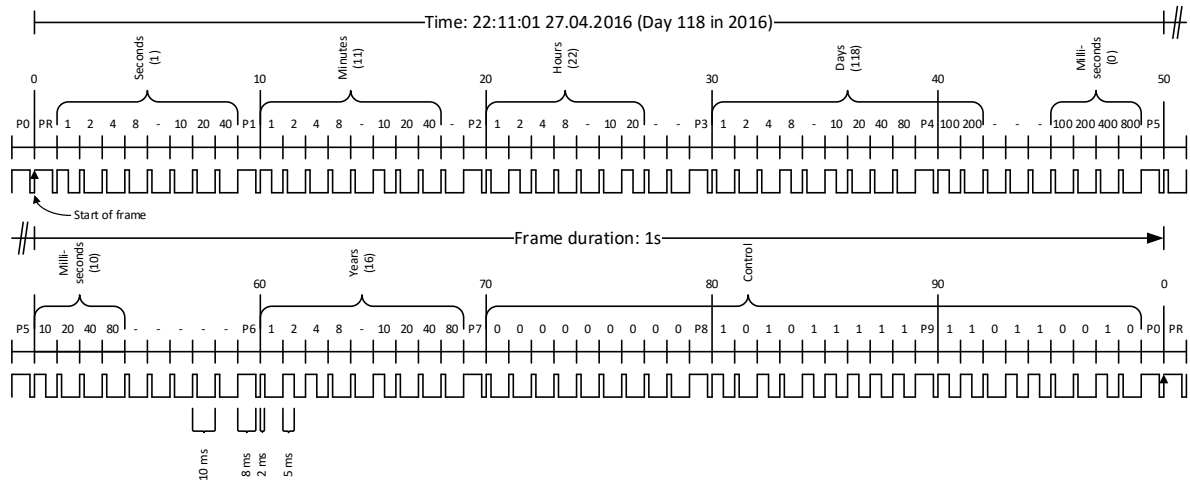

Figure 5: IRIG-G G006/B146 time frame

For high accuracy synchronization delays have to be compensated for.
An IRIG network is normally a one-to-many configuration: one IRIG master syn-chronizes multiple IRIG slaves of different distance from the master.

2.2 Delays

There are two kinds of delays in an IRIG Network. One is the input delay of the IRIG signal from the connector to the core (or also the Sine Wave Encoding ADC read-ing); this shall be constant and is compensated for. The second delay is the propa-gation delay of the signal from the master to the slave. This is dependent on the cable length and medium: 15cm of copper cable are equal to roughly 1ns of propa-gation delay. This delay can be set in the core, e.g. for compensation of the cable length to a time server on the building's roof.

2.3 UTC vs TAI time bases

IRIG time frames contain the time of day on UTC base. UTC has an offset to TAI which is the time base normally used for the Counter Clock. This time offset can be set in the core so the local clock can still run on a TAI base. UTC in comparison to TAI or GPS time has so called leap seconds. A leap second is an additional second which is either added or subtracted from the current time to adjust for the earth rotation variation over time. Until 2016 UTC had additional 36 leap seconds, there-fore TAI time is currently 36 seconds ahead of UTC. The issue with UTC time is, that the time makes jumps with the leap seconds which may cause that synchro-nized nodes go out of sync for a couple of seconds. Leap seconds are normally

introduced at midnight of either the 30 of June or 31 of December. For an additional leap second the seconds counter of the UTC time will count to 60 before wrapping around to zero, for one fewer leap second the UTC second counter will wrap directly from 58 to 0 by skipping 59 (this has not happened yet).

Be aware that this core takes no additional precautions to handle leap seconds, so it will make a time jump at a UTC leap second and will lose synchronization since it thinks that it has an offset of one second at tries to readjust this offset. A way to avoid this is to disable the adjustment at the two dates right before midnight (e.g. one minute earlier), wait for the leap second to happen, fetch some time server to get the new offset between TAI and UTC, set this offset to the core and enable the core again. This way the local clock on TAI base makes no jump since the new offset is already taken into account. The only issue with this is that for the time around midnight the clock is free running without a reference.

3 Register Set

This is the register set of the IRIG Slave Clock. It is accessible via AXI4Lite Memory Mapped. All registers are 32bit wide, no burst access, no unaligned access, no byte enables, no timeouts are supported. Register address space is not contiguous. Register addresses are only offsets in the memory area where the core is mapped in the AXI inter connects. Non existing register access in the mapped memory area is answered with a slave decoding error.

3.1 Register Overview

Registerset Overview			
Name	**Description**	**Offset**	**Access**
Irig SlaveControl Reg	IRIG Slave Enable Control Register	0x00000000	RW
Irig SlaveStatus Reg	IRIG Slave Error Status Register	0x00000004	WC
Irig SlaveVersion Reg	IRIG Slave Version Register	0x0000000C	RO
Irig SlaveCorrection Reg	IRIG Slave Second Corrections Register	0x00000010	RW
Irig SlaveControlBits Reg	Irig Slave Control Bits Register	0x00000014	RO
Irig SlaveCableDelay Reg	Irig Slave Cable Delay Register	0x00000020	RW
Irig SlaveYearReg	Irig Slave Year Register	0x00000024	RW

Table 4:   Register Set Overview

3.2 Register Descriptions

3.2.1 General

3.2.1.1 IRIG Slave Control Register

Used for general control over the IRIG Slave Clock, all configurations on the core shall only be done when disabled.

IRIG SlaveControl Reg

Reg Description

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
						IRIG_MODE							IRIG_CODE										YEAR_VAL							IRIG_AM	ENABLE
RO						RW		RO					RW			RO							RW	RO						RW	RW

Reset: 0x000X0000

Offset: 0x0000

Name	Description	Bits	Access
-	Reserved, read 0	Bit: 31:26	RO
IRIG_MODE	IRIG-B = 1, IRIG-G = 2, others NON	Bit: 25:24	RW
-	Reserved, read 0	Bit: 23:19	RO

IRIG_CODE	IRIG-B Code B00X (e.g. 7 = B007/B127) (default by generic)	Bit: 18:16	RW
-	Reserved, read 0	Bit: 15:9	RO
YEAR_VAL	Set the year information (autocleared)	Bit: 8	RW
-	Reserved, read 0	Bit: 7:2	RO
IRIG_AM	Use IRIG AM input	Bit: 1	RW
ENABLE	Enable	Bit: 0	RW

3.2.1.2 IRIG Slave Status Register

Shows the current status of the IRIG Slave Clock.

Irig SlaveStatus Reg																															
Reg Description																															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ERROR																															ERROR
WC	RO																														WC
Reset: 0x00000000																															
Offset: 0x0004																															

Name	Description	Bits	Access
-	Reserved, read 0	Bit: 31:1	RO
ERROR	IRIG Error (sticky)	Bit: 0	WC

3.2.1.3 IRIG Slave Version Register

Version of the IP core, even though is seen as a 32bit value, bits 31 down to 24 represent the major, bits 23 down to 16 the minor and bits 15 down to 0 the build numbers.

Irig SlaveVersion Reg																															
Reg Description																															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
VERSION																															
RO																															
0xXXXXXXXX																															
Offset: 0x000C																															

Name	Description	Bits	Access
VERSION	Version of the core	Bit: 31:0	RO

3.2.1.4 IRIG Slave Correction Register

Correction register to compensate for leap seconds between the different time domains. IRIG is UTC time, all other time in the system is TAI, this leads to a correction of 36 seconds by 2016.

Irig SlaveCorrection Reg																															
Reg Description																															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
COR_SIGN	COR_S																														
RW	RW																														
Reset: 0x00000000																															
Offset: 0x0010																															

Name	Description	Bits	Access
COR_SIGN	Correction sign	Bit: 31	RW
COR_S	Correction in seconds to the time extracted from the IRIG => used to convert between TAI, UTC and GPS (leap seconds)	Bit: 30:0	RW

3.2.1.5 IRIG Slave Control Bits Register

Received Control bits. Representing Bit50-Bit58 & Bit60-Bit68 & Bit70-Bit78 of the IRIG frame: Bit50 => Bit0, Bit78 => Bit26 of the register. When IRIG-B004/B005 is used only Bit60-Bit68 & Bit70-Bit78 are representing control bits in the register, Bit50-Bit58 are representing the year information.

Irig SlaveControlBits Reg																															
Reg Description																															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
				'												CONTROL_BITS															
		RO														RO															
0x00000000																															
Offset: 0x0014																															

Name	Description	Bits	Access
-	Reserved, read 0	Bit:31:27	RO
CONTROL_BITS	Received Control bits for IRIG-B004/B005	Bit: 26:0	RO

3.2.1.6 IRIG Slave Cable Delay Register

This register allows to compensate for the propagation delay of the cable between the IRIG master and the IRIG slave. To calculate the delay a rule of thumb says around 1ns per 15cm of cable.

Irig SlaveCableDelay Reg																															
Reg Description																															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
																CABLE_DELAY															
RO																RW															
Reset: 0x00000000																															
Offset: 0x0020																															

Name	Description	Bits	Access
-	Reserved, read 0	Bit: 31:16	RO
CABLE_DELAY	Cable delay of cable to master in nanoseconds (15cm is around 1ns)	Bit: 15:0	RW

3.2.1.7 IRIG Slave Year Register

This register allows to set the Year information in case IRIG-B/GXX3 is used where no year information is available via IRIG. First the year needs to written and then in the Control register the YEAR_VAL flag set. At this moment the year information will be taken over and based on the Day information on IRIG the year also autoincremented. Whenever the YEAR_VAL flag is set again the year is taken over.

Irig SlaveCableDelay Reg																															
Reg Description																															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
																				YEAR											
RO																				RW											
Reset: 0x00000000																															
Offset: 0x0024																															

Name	Description	Bits	Access
-	Reserved, read 0	Bit: 31:12	RO
YEAR	Year information in case IRIG Code 0-3 is used (1970-2069)	Bit: 11:0	RW

4 Design Description

The following chapters describe the internals of the IRIG Slave Clock: starting with the Top Level, which is a collection of subcores, followed by the description of all subcores.

4.1 Top Level – Irig Slave

4.1.1.1 Parameters

The core must be parametrized at synthesis time. There are a couple of parameters which define the final behavior and resource usage of the core.

Name	Type	Size	Description
StaticConfig_Gen	boolean	1	If Static Configuration or AXI is used
IrigSineWave Support_Gen	boolean	1	If IRIG AM is supported
IrigBSupport_Gen	boolean	1	If IRIG-B is supported
IrigGSupport_Gen	boolean	1	If IRIG-G is supported
ClockClkPeriod Nanosecond_Gen	natural	1	Clock Period in Nanosecond: Default for 50 MHz = 20 ns
InputDelay Nanosecond_Gen	natural	1	Input delay of the IRIG from the connector to the input signal.
DefaultCode_Gen	std_logic_vector	3	Default IRIG-B Code (e.g. "111" => 7 => IRIG-B007)
AxiAddressRange Low_Gen	std_logic_vector	32	AXI Base Address
AxiAddressRange High_Gen	std_logic_vector	32	AXI Base Address plus Registerset Size Default plus 0xFFFF
Sim_Gen	boolean	1	If in Testbench simulation mode: true = Simulation, false = Synthesis

Table 5: Parameters

4.1.1.2 Structured Types

4.1.1.2.1 Clk_Time_Type

Defined in Clk_Package.vhd of library ClkLib

Type represents the time used everywhere. For this type overloaded operators + and – with different parameters exist.

Field Name	Type	Size	Description
Second	std_logic_vector	32	Seconds of time
Nanosecond	std_logic_vector	32	Nanoseconds of time
Fraction	std_logic_vector	2	Fraction numerator (mostly not used)
Sign	std_logic	1	Positive or negative time, 1 = negative, 0 = positive.
TimeJump	std_logic	1	Marks when the clock makes a time jump (mostly not used)

Table 6:   Clk_Time_Type

4.1.1.2.2 Clk_TimeAdjustment_Type

Defined in Clk_Package.vhd of library ClkLib

Type represents the time used everywhere. For this type overloaded operators + and – with different parameters exist.

Field Name	Type	Size	Description
TimeAdjustment	Clk_Time_Type	1	Time to adjust
Interval	std_logic_vector	32	Adjustment interval, for the drift correction this is the denumerator of the rate in nanoseconds (TimeAdjustment every Interval = drift rate), for offset correction this is the period in which the time shall be corrected (TimeAdjustment in Interval), for setting the time this has no meaning.

Valid	std_logic	1	Whether the Adjustment is valid or not

Table 7:   Clk_TimeAdjustment_Type

4.1.1.2.3 Irig_SlaveStaticConfig_Type

Defined in Irig_SlaveAddrPackage.vhd of library IrigLib

This is the type used for static configuration.

Field Name	Type	Size	Description
IrigMode	Irig_Mode_Type	3	Define the modes: Unknown_E, IrigB_E, IrigG_E
IrigCode	std_logic_vector	3	IRIG-B Mode: 0=B000, 7=B007
IrigSineWave	std_logic	1	If IRIG AM shall be used
IrigYear	std_logic_vector	12	Manual Year for B000-B003
Correction	Clk_Time_Type	1	Time to correct the parsed time to correct UTC to TAI or another base.
CableDelay	std_logic_vector	16	Compensation value for the cable delay between master and slave in Nanoseconds: 1ns = 15cm

Table 8:   Irig_SlaveStaticConfig_Type

4.1.1.2.4 Irig_SlaveStaticConfigVal_Type

Defined in Irig_SlaveAddrPackage.vhd of library IrigLib

This is the type used for valid flags of the static configuration.

Field Name	Type	Size	Description
IrigYear_Val	std_logic	1	Set the manual Year
Enable_Val	std_logic	1	Enables the IRIG Slave

Table 9:   Irig_SlaveStaticConfigVal_Type

4.1.1.2.5 Irig_SlaveStaticStatus_Type

Defined in Irig_SlaveAddrPackage.vhd of library IrigLib

This is the type used for static status supervision.

Field Name	Type	Size	Description
CoreInfo	Clk_CoreInfo_ Type	1	Info about the Cores state
UtcInfo	Clk_UtcInfo_Typ	1	Info about UTC details
IrigMode	Irig_Mode_Type	3	Define the modes: Unknown_E, IrigB_E, IrigG_E
IrigCode	std_logic_vector	3	IRIG-B Mode: 0=B000, 7=B007
IrigSineWave	std_logic	1	If IRIG AM shall be used
ControlBits	std_logic_vector	27	Received Control Bits

Table 10:   Irig_SlaveStaticStatus_Type

4.1.1.2.6 Irig_SlaveStaticStatusVal_Type

Defined in Irig_SlaveAddrPackage.vhd of library IrigLib

This is the type used for valid flags of the static status supervision.

Field Name	Type	Size	Description
CoreInfo_Val	std_logic	1	Core Info valid
UtcInfo_Val	std_logic	1	UTC Info valid

Table 11:   Irig_SlaveStaticStatusVal_Type
4.1.1.3 Entity Block Diagram

Figure 6:   IRIG Slave Clock

4.1.1.4 Entity Description

Rx Processor

This module handles the incoming IRIG signal. It decodes the IRIG input data stream and converts the signal from a DCLS encoded PWM signal to a BCD encoded time and converts it then into UTC in time of day format. In parallel it detects the start of second condition and generates a PPS. Then it converts the UTC time in time of day format into TAI format in seconds since 1.1.1970 without leap seconds. It also takes a timestamp of the rising edge of the PPS, takes the propagation delay of the cable into account, calculates the offset and the drift against the encoded time and adjusts the local clock.
See 4.2.1 for more details.

Registerset

This module is an AXI4Lite Memory Mapped Slave. It provides access to all registers and allows configuring the IRIG Slave Clock. It can be configured to either run in AXI or StaticConfig mode. If in StaticConfig mode, the configuration of the registers is done via signals and can be easily done from within the FPGA without CPU. If in AXI mode, an AXI Master has to configure the registers with AXI writes to the registers, which is typically done by a CPU
See 4.2.2 for more details.

4.1.1.5 Entity Declaration

Name	Dir	Type	Size	Description
Generics				
General				
StaticConfig_Gen	-	boolean	1	If Static Configuration or AXI is used
IrigSineWave Support_Gen	-	boolean	1	If IRIG AM is supported
IrigBSupport_Gen	-	boolean	1	If IRIG-B is supported
IrigGSupport_Gen	-	boolean	1	If IRIG-G is supported
ClockClkPeriod Nanosecond_Gen	-	natural	1	Integer Clock Period
InputDelay Nanosecond_Gen	-	natural	1	Input delay of the IRIG from the connector to the input signal.
DefaultCode_Gen	-	std_logic_vector	3	Default IRIG-B Code
AxiAddressRange Low_Gen	-	std_logic_vector	32	AXI Base Address

4.2 Design Parts

The IRIG Slave Clock core consists of a couple of subcores. Each of the subcores itself consist again of smaller function block. The following chapters describe these subcores and their functionality.
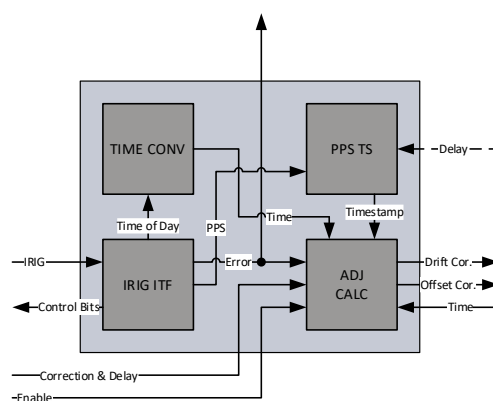

4.2.1 RX Processor

4.2.1.1 Entity Block Diagram

Figure 7:   RX Processor

4.2.1.2 Entity Description

IRIG Interface Adapter

This module decodes the IRIG input data stream and converts the signal from a DCLS encoded PWM signal to a BCD encoded time and converts it then into UTC in time of day format. In parallel it detects the start of second condition and generates a PPS. It also extracts the Control Bits (including the Year part)

PPS Timestamper

This module takes a timestamp. of the Counter Clock at the detection of the rising edge of the PPS and compensates the input delay and potential delay from the Sine Wave Decoding. The input PPS is generated at the detection of the Mark symbol by the IRIG Interface Adapter

Time Converter

This module converts the time from the Time of Day format: hh:mm:ss ddd:yyyy into seconds since midnight 1.1.1970. It loops over the years and days taking the

leap years into account and finally adds the seconds of the hours, minutes and seconds. After this conversion, a final correction is done to adjust the second to the next second. Then this time is passed to the adjustment calculation module.

For IRIG-B/GXX0-3 the Year information is coming from the register, since the IRIG stream is lacking year information. The year shall be set once after powerup and based on the Days wraparound automatically incremented.

Adjustment Calculation

This module calculates the drift and offset of the local clock and corrects it. It takes the cable delay and additional correction into account for the offset correction. After enabling or error detection the calculation waits for two consecutive calculations before adjusting the clock again.

4.2.1.3 Entity Declaration

Name	Dir	Type	Size	Description
Generics				
General				
ClockClkPeriod Nanosecond_Gen	-	natural	1	Clock Period in Nanosecond
IrigSineWave Support_Gen	-	boolean	1	If IRIG AM is supported
IrigBSupport_Gen	-	boolean	1	If IRIG-B is supported
IrigGSupport_Gen	-	boolean	1	If IRIG-G is supported
Sim_Gen	-	boolean	1	If in Testbench simulation mode
RX Processor				
InputDelay Nanosecond_Gen	-	natural	1	Input delay of the IRIG from the connector to the input signal.
Ports				
System				
SysClk_ClkIn	in	std_logic	1	System Clock
SysRstN_RstIn	in	std_logic	1	System Reset
Timer				

Timer1ms_EvtIn	in	std_logic	1	Millisecond timer adjusted with the Clock
Time Input				
ClockTime_DatIn	in	Clk_Time_Type	1	Adjusted PTP Clock Time
ClockTime_ValIn	in	std_logic	1	Adjusted PTP Clock Time valid
IRIG Mode Input				
IrigMode_DatIn	in	Irig_Mode_Type	1	IRIG Mode: Unknown_E, IrigB_E, IrigG_E
IrigCode_DatIn	in	std_logic_vector	3	IRIG-B Code
IrigSineWave_DatIn	in	std_logic	1	IRIG AM
IRIG Year Input				
IrigYear_DatIn	in	std_logic_vector	12	Year information for IRIG b/GXX0-3
IrigYear_ValIn	in	std_logic	1	Year information to set
IRIG Year Output				
IrigYear_DatOut	out	std_logic_vector	12	Year information for IRIG b/GXX0-3
IrigYear_ValOut	out	std_logic	1	Year information was updated
IRIG Error Output				
Irig_ErrOut	out	std_logic_vector	1	Indicates an error in the decoding
Enable Input				
Enable_EnaIn	in	std_logic	1	Enables the correction and supervision
IRIG Cable Delay Input				
IrigCableDelay_DatIn	in	std_logic_vector	16	Propagation delay of the IRIG signal from the master source to the connector.
IRIG Correction Input				
IrigCorrection_DatIn	in	Clk_Time_Type	1	Additional correction to convert from UTC to a different

				time format with an offset
IRIG Control Bits Output				
IrigControlBits_ DatOut	out	std_logic_vector	27	Control Bits received for IRIG-B000/B001/B004/B005
IRIG Input				
Irig_DatIn	in	std_logic	1	IRIG input from an IRIG Master
IRIG AM Delay Input				
SineWaveDelay Nanosecond_DatIn	in	natural	1	Delay of a Sine Wave Decoder
Offset Adjustment Output				
OffsetAdjustment _DatOut	out	Clk_TimeAdjustment _Type	1	Calculated new Offset between Master and Slave
OffsetAdjustment _ValOut	out	std_logic;	1	Calculated new Offset valid
Drift Adjustment Output				
DriftAdjustment _DatOut	out	Clk_TimeAdjustment _Type	1	Calculated new Drift between Master and Slave
DriftAdjustment _ValOut	out	std_logic;	1	Calculated new Drift valid
Offset Adjustment Input				
OffsetAdjustment _DatIn	in	Clk_TimeAdjustment _Type	1	Calculated new Offset after the PI Servo loop
OffsetAdjustment _ValIn	in	std_logic;	1	Calculated new Offset after the PI Servo loop valid
Drift Adjustment Input				
DriftAdjustment _DatIn	in	Clk_TimeAdjustment _Type	1	Calculated new Drift after the PI Servo loop
DriftAdjustment _ValIn	in	std_logic	1	Calculated new Drift after the PI Servo loop valid

## 4.2.2 Registerset

4.2.2.1 Entity Block Diagram

Figure 8:   Registerset

4.2.2.2 Entity Description

Register Set

This module is an AXI4Lite Memory Mapped Slave. It provides access to all registers and allows configuring the IRIG Slave Clock. AXI4Lite only supports 32 bit wide data access, no byte enables, no burst, no simultaneous read and writes and no unaligned access. It can be configured to either run in AXI or StaticConfig mode. If in StaticConfig mode, the configuration of the registers is done via signals and can be easily done from within the FPGA without CPU. For each parameter a valid signal is available, the enable signal shall be set last (or simultaneously). To change configuration parameters the clock has to be disabled and enabled again, the cable delay value and correction can be changed at runtime. If in AXI mode, an AXI Master has to configure the registers with AXI writes to the registers, which is typically done by a CPU. Parameters can in this case also be changed at runtime.

4.2.2.3 Entity Declaration

Name	Dir	Type	Size	Description
Generics				
Register Set				
StaticConfig_Gen	-	boolean	1	If Static Configuration or AXI is used
IrigBSupport_Gen	-	boolean	1	If IRIG-B is supported
IrigGSupport_Gen	-	boolean	1	If IRIG-G is supported

DefaultCode_Gen	-	std_logic_vector	3	Default IRIG-B Code
AxiAddressRange Low_Gen	-	std_logic_vector	32	AXI Base Address
AxiAddressRange High_Gen	-	std_logic_vector	32	AXI Base Address plus Registerset Size

IRIG Error Input				
Irig_ErrIn	in	std_logic_vector	1	Indicates an error either in the filter or because of missing IRIG

IRIG Cable Delay Output				
IrigCable Delay_DatOut	in	std_logic_vector	16	Propagation delay of the IRIG signal from the master source to the connector.
IRIG Control Bits Input				
IrigControlBits_ DatIn	in	std_logic_vector	27	Control Bits received for IRIG-B000/B001/B004/B005
Enable Output				
IrigSlave Enable_DatOut	out	std_logic	1	Enables the correction and supervision

Table 14:   Registerset

4.3 Configuration example

In both cases the enabling of the core shall be done last, after or together with the configuration.

4.3.1 Static Configuration

```
constant IrigStaticConfigSlave_Con : Irig_SlaveStaticConfig_Type := (
  IrigMode              => IrigB_E, -- IRIG-B
  IrigCode              => std_logic_vector(to_unsigned(7, 3)), -- IRIG-B007
  IrigSineWave          => '0', -- DCLS
  IrigYear              => std_logic_vector(to_unsigned(2025, 12)),
  Correction            => (
    Second              => x"00000024", -- UTC 36 leap seconds
    Nanosecond          => (others => '0'), -- no nanoseconds
    Fraction            => (others => '0'), -- no fractions
    Sign                => '0', -- UTC correct in positive
    TimeJump            => '0'), -- no
  CableDelay            => (others => '0')
);

constant IrigStaticConfigValSlave_Con : Irig_SlaveStaticConfigVal_Type := (
  IrigYear_Val              => '0',
  Enable_Val                => '1'
);
```

Figure 9:   Static Configuration

The cable delay can be changed at runtime. It is always valid. The year can also set whenever required by the code

4.3.2 AXI Configuration

The following code is a simplified pseudocode from the testbench: The base address of the IRIG Slave Clock is 0x10000000.

```
-- IRIG SLAVE
-- Config
-- correction of plus 36 second to convert UTC to TAI
AXI WRITE 10000010 00000024
-- Set cable delay to 35 ns
AXI WRITE 10000020 00000023
-- enable IRIG B007 Slave
AXI WRITE 10000000 01070001
```

Figure 10:   AXI Configuration

In the example the Cable delay is first set to 35ns and the Correction is set to plus 36 seconds then the core is enabled.

4.4 Clocking and Reset Concept

4.4.1 Clocking

To keep the design as robust and simple as possible, the whole IRIG Slave Clock, including the Counter Clock and all other cores from NetTimeLogic are run in one clock domain. This is considered to be the system clock. Per default this clock is 50MHz. Where possible also the interfaces are run synchronous to this clock. For clock domain crossing asynchronous fifos with gray counters or message patterns with meta-stability flip-flops are used. Clock domain crossings for the AXI interface is moved from the AXI slave to the AXI interconnect.

Clock	Frequency	Description
System		
System Clock	50MHz (Default)	System clock where the PS runs on as well as the counter clock etc.
IRIG Interface		
IRIG	100 Hz	No clock, asynchronous data signal.
AXI Interface		
AXI Clock	50MHz (Default)	Internal AXI bus clock, same as the system clock

Table 15:   Clocks

4.4.2 Reset

In connection with the clocks, there is a reset signal for each clock domain. All resets are active low. All resets can be asynchronously set and shall be synchronously released with the corresponding clock domain. All resets shall be asserted for the first couple (around 8) clock cycles. All resets shall be set simultaneously and released simultaneously to avoid overflow conditions in the core. See the reference designs top file for an example of how the reset shall be handled.

Reset	Polarity	Description
System		
System Reset	Active low	Asynchronous set, synchronous release with the system clock
AXI Interface		

AXI Reset	Active low	Asynchronous set, synchronous release with the AXI clock, which is the same as the system clock

Table 16: Resets

5 Resource Usage

Since the FPGA Architecture between vendors and FPGA families differ there is a split up into the two major FPGA vendors.

5.1 Intel/Altera (Cyclone V)

Configuration	FFs	LUTs	BRAMs	DSPs
Minimal (Static configuration and only IRIG-B)	1431	4585	0	0
Maximal (AXI configuration and IRIG-B and IRIG-G)	1579	5365	0	0

Table 17: Resource Usage Intel/Altera

5.2 AMD/Xilinx (Artix 7)

Configuration	FFs	LUTs	BRAMs	DSPs
Minimal (Static configuration and only IRIG-B)	1426	4178	0	0
Maximal (AXI configuration and IRIG-B and IRIG-G)	1574	4842	0	0

Table 18: Resource Usage AMD/Xilinx

6 Delivery Structure

```

 |-Testbench                    -- IRIG library cores testbench sources and sim/log

SIM                             -- SIM library folder
 |-Doc                          -- SIM library command documentation
 |-Package                      -- SIM library package sources
 |-Testbench                    -- SIM library testbench template sources
 |-Tools                        -- SIM simulation tools
```

7 Testbench

The Irig Slave testbench consist of 3 parse/port types: AXI, CLK and IRIG. The IRIG TX port takes the CLK port time as reference and generates the IRIG stream aligned with the time from the CLK. The IRIG RX port takes the time of the Clock instance as reference and the IRIG stream from the IRIG TX port. Once the clock is synchronized the CLK port and Clock generated time should be phase and frequency aligned. In addition, for configuration and result checks an AXI read and write port is used in the testbench and for accessing more than one AXI slave also an AXI interconnect is required.
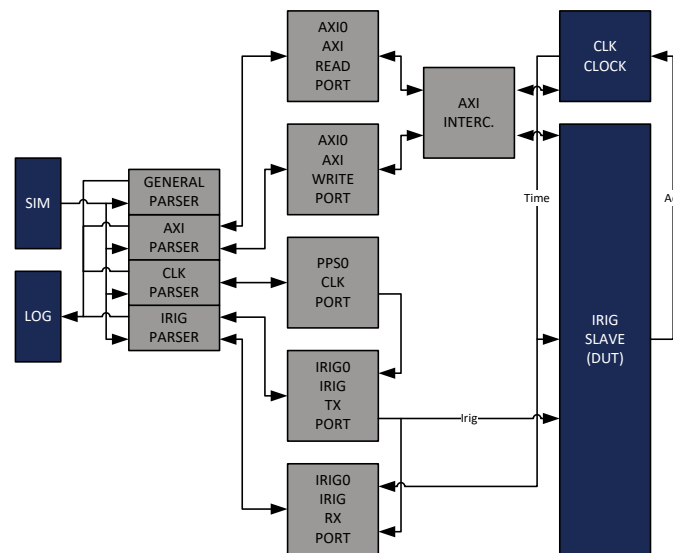

Figure 11:   Testbench Framework

For more information on the testbench framework check the Sim_ReferenceManual documentation.

With the Sim parameter set the time base for timeouts are divided by 1000 to 100000 to speed up simulation time.

7.1 Run Testbench

1. Run the general script first

```
source XXX/SIM/Tools/source_with_args.tcl
```

2. Start the testbench with all test cases

```
src XXX/IRIG/Testbench/Core/IrigSlave/Script/run_Irig_Slave_Tb.tcl
```

3. Check the log file LogFile1.txt in the XXX/IRIG/Testbench/Core/IrigSlave/Log/ folder for simulation results.

8 Reference Designs

The IRIG Slave reference design contains a PLL to generate all necessary clocks (cores are run at 50 MHz), an instance of the IRIG Slave Clock IP core and an instance of the Adjustable Counter Clock IP core (needs to be purchased separately). Optionally it also contains an instance of an PPS Master Clock IP core (has to be purchased separately). To instantiate the optional IP core, change the corresponding generic (PpsMasterAvailable_Gen) to true via the tool specific wizards.

The Reference Design is intended to be connected to any IRIG Master. The Phase and Frequency is corrected via the IRIG Slave Clock. The PPS Master Clock is used to create a PPS output which is compensated for the output delay and has a configurable duty cycle, if not available an uncompensated PPS is directly generated out of the MSB of the Time. Via the dip switches the cable delay can be entered in 5ns steps.

All generics can be adapted to the specific needs.
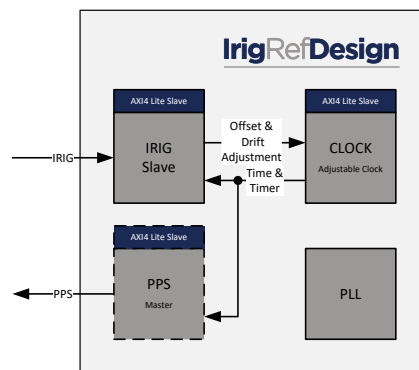

Figure 12:   Reference Design

8.1 Intel/Altera: Terasic SocKit

The SocKit board is an FPGA board from Terasic Inc. with a Cyclone V SoC FPGA from Intel/Altera. (http://www.terasic.com.tw/cgi-bin/page/archive.pl?Language=English&CategoryNo=205&No=816)

1. Open Quartus 16.x
2. Open Project /IRIG/Refdesign/Altera/SocKit/IrigSlave/IrigSlave.qpf
3. If the optional core PPS Master Clock is available add the files from the corresponding folders (PPS/Core, PPS/Library and PPS/Package)
4. Change the generics (PpsMasterAvailable_Gen) in Quartus (in the settings menu, not in VHDL) to true for the optional cores that are available.

5. Rerun implementation
6. Download to FPGA via JTAG
Figure 13:   SocKit (source Terasic Inc)

For the ports on the HSMC connector the GPIO to HSMC adapter from Terasic Inc. was used.

8.2 AMD/Xilinx: Digilent Arty

The Arty board is an FPGA board from Digilent Inc. with an Artix7 FPGA from AMD/Xilinx. (http://store.digilentinc.com/arty-board-artix-7-fpga-development-board-for-makers-and-hobbyists/)

1. Open Vivado 2019.1
   Note: If a different Vivado version is used, see chapter 8.3.
2. Run TCL script /IRIG/Refdesign/Xilinx/Arty/IrigSlave/IrigSlave.tcl
   a. This has to be run only the first time and will create a new Vivado Pro-ject
3. If the project has been created before open the project and do not rerun the project TCL

4. If the optional core PPS Master Clock is available add the files from the corresponding folders (PPS/Core, PPS/Library and PPS/Package) to the corresponding Library (PpsLib).

5. Change the generics (PpsMasterAvailable_Gen) in Vivado (in the settings menu, not in VHDL) to true for the optional cores that are available.

6. Rerun implementation

7. Download to FPGA via JTAG
Figure 14:   Arty (source Digilent Inc)

8.3 AMD/Xilinx: Vivado version

The provided TCL script for creation of the reference-design project is targeting AMD/Xilinx Vivado 2019.1.

If a lower Vivado version is used, it is recommended to upgrade to Vivado 2019.1 or higher.

If a higher Vivado version is used, the following steps are recommended:

- Before executing the project creation TCL script, the script's references of Vivado 2019 should be manually replaced to the current Vivado version. For example, if version Vivado 2022 is used, then:
  - The statement occurrences:

        set_property flow "Vivado Synthesis 2019" $obj

    shall be replaced by:

        set_property flow "Vivado Synthesis 2022 $obj

- o The statement occurrences:

  ```
  set_property flow "Vivado Implementation 2019" $obj
  ```

  shall be replaced by:

  ```
  set_property flow "Vivado Implementation 2022" $obj
  ```

- After executing the project creation TCL script, the AMD/Xilinx IP cores, such as the Clocking Wizard core, might be locked and a version upgrade might be required. To do so:
  1. At "Reports" menu, select "Report IP Status".
  2. At the opened "IP Status" window, select "Upgrade Selected". The tool will upgrade the version of the selected IP cores.
